

Task 2 - Evaluate JavaParser on Complex Java Source

Objective:

Use a real or synthetic Java source file that includes a variety of language features (e.g., comments, annotations, nested types, initializers) to perform a practical evaluation of JavaParser.

If the full test project (from Task 1) is already available, reuse it. Otherwise, prepare a smaller sample manually with the following elements:

- Class-level and field-level annotations
- Nested classes or interfaces
- Different types of comments (Javadoc, single-line, multi-line, floating)
- Lambda and stream expressions
- Fields depending on each other
- Static and instance initializers

What to do:

1. Parse the code using JavaParser.
2. Modify the order of class members.
3. Serialize the AST back into source code.
4. Verify that the output is structurally and syntactically valid.
5. Document your findings.

Evaluation Criteria:

Perform analysis according to the following aspects:

Criterion	JavaParser
Support for latest Java versions	
AST quality	
Documentation level	
Integration complexity	
Code re-serialization (pretty-printing)	
Annotation processing	
Nested class handling	
Dependency tracking (e.g. between fields)	
AST API flexibility	

Results should be recorded in a structured format, e.g. table or bullet points.
No need to draw final conclusions at this stage — focus on data collection.
